Stable Power Supply Thanks to Hydropower

Reconstructing of the historical dam with local raw materials.

In Indonesia, a hydroelectric power plant is being renovated and recommissioned, and renewable power fed into the regional power supply system. Through the replacement of diesel-based power, greenhouse gas emissions are lowered.

An obsolete hydro power plant in need of renovation, whose current output of 75 kW lies clearly below its possible capacity, is being restored, expanded and connected to the regional power supply system in a 3-step process. For this, the existing infrastructure is to be used as far as possible. Nevertheless, the better part of the technical and electronic equipment has to be replaced with new components. The completed plant has a design capacity of 935 kW and will annually reduce up to 4,500 tonnes of CO₂.

In addition to the contribution to the protection of the climate, the project brings improvement of the economic, social and ecological situation in the region. Power failures due to insufficient capacity are extremely frequent.

Project type: Hydro power
Project location: Salido Kecil, Indonesia
Project status: In operation, credits available
Annual CO₂ reduction: 3,716 t
Situation without project
Regional electricity mix

Impressions

The aqueduct takes the water from the dam and its reservoir through the jungle to the pressure pipeline.

The kilometre long aqueduct was built at the beginning of the 20th century during the Dutch colonization, and runs through the jungle of western Sumatra.

47 people trained
44.16 GWh renewable energy generated
13 long-term jobs created
in rural Indonesia. Through this project, the local population benefits from a more stable power supply system - a central requirement for the local economy. In addition, through the renovation and operation of the plant, new employment opportunities are created, and the environment benefits from the substitution of diesel-based energy. There is no additional contamination of the environment since the power plant is being built on an existing infrastructure.

The demand for power in Indonesia has been greatly increasing year after year, and the renewable energies - especially hydro power - show great potential in this country. Such projects are to contribute as pilot projects to making it possible that the large growth of energy demand can be covered as sustainably as possible.

The first restored turbine was put in operation in August 2007 and has been running since without problems. The commissioning of the second turbine took place in July 2009 and of the third turbine in July 2013.

This project contributes to 3 SDGs:

47 people trained on different aspects of the project.

44.16 GWh renewable energy produced.

13 long-term positions created
