Composting Avoids Methane Emissions

The eco park before the refurbishment. A huge waste mountain towers in front of the recycling pilot building.

The climate protection project on Bali composes organic waste that previously had to be dumped. In this way, methane emissions from the tip can be avoided and high-value compost is being produced.

116,094 tonnes of organic waste collected
14,000 tonnes of compost produced
74,200 tonnes of CO₂ avoided

Bali, the most important tourism destination in Indonesia, has a growing waste problem which is already having an impact on the tourism sector. In the so far untouched landscape, waste is being illegally disposed of in rivers and lakes, canals, and along the streets. The small amount of gathered waste from the project region Gianyar, in the southeast of the island, is disposed of on a tip in the vicinity of the village Temesi. The methane developing from such a tip is neither collected nor burned and therefore rises unhindered into the atmosphere. Methane is one of the most harmful greenhouse gases and contributes in large quantities to the destabilization of the climate.

Project type:
Waste Management and Compost

Project location:
Province of Bali, Town of Temesi

Project status:
In operation, credits available

Annual CO₂ reduction:
7,671 t

Situation without project
Methane emissions from landfill

Contribution to the SDGs

Project standard

United Nations
Climate Change

CER

Impressions

The eco park after the refurbishment. The pilot building has been converted to an education centre.

Trucks bringing organic waste to the plant.
In the face of the deterioration of the situation on-site, the Rotary Club of Bali Ubud decided to counteract this problem and planned and implemented a composting plant.

85 per cent of the waste in this region is derived from organic material, which can be composted and does not have to be brought to the tip. Another 5 percent, mainly plastics, can be recycled so that after the implementation of the project only 10 percent are dumped on the tip. Since aerobic composting does not cause methane emissions, a considerable reduction of greenhouse gas emissions can be achieved.

In addition to the effect on the climate, the local population also benefits, in that the air pollution from the tip is reduced, the waste volume is reduced by around 90 percent, and different jobs on-site are created.

All parties involved hope that through this model project, which was started in May 2008, composting will spread to new areas on Bali and all of Indonesia. A theme park next to the plant will sensitize visitors to the waste problem and give them a better understanding of composting.

This project contributes to 8 SDGs:

- **2 Zero Hunger**: The use of compost increases the yield of the farmers.
- **3 Good Health and Well-being**: The reduction of waste reduces the contamination of water and soil.
- **4 Quality Education**: The visitors centre educates school classes about sustainable development, waste management and climate change.
- **8 Decent Work and Economic Growth**: 124 jobs created.
- **11 Sustainable Cities and Communities**: 116,094 tonnes of organic waste collected.
- **12 Responsible Consumption and Production**: Over 14,000 tonnes of compost have been produced and lead to a reduction of chemical fertilizer usage.
74,200 tonnes of CO₂ avoided.

The project activity was realised thanks to the initiative and seedfunding from a Swiss rotary club.
